Graded Lab 2

Problem Statement

You are required to write a C++ program that demonstrates **process creation** using the `fork()` system call. The program should work as follows:

1. Implement a function `is_prime(int num)` that checks whether a given number is prime.
2. Implement another function `findPrime(int start, int end)` that prints all prime numbers in the given range `[start, end]`.
3. In the `main()` function:
    - Use the `fork()` system call to create a **child process**.
    - The **child process** should find and print all prime numbers **greater than 50 but less than 100**.
    - The **parent process** should wait for the child to finish, and then print all prime numbers **between 2 and 49**.
4. Display appropriate messages to clearly indicate which process (parent/child) is executing.
